## Unit – 4 ADO.NET & Database

### Q-1 What is ADO.NET? Explain ADO .NET Architecture.

- ADO.NET (ActiveX Data Object for .NET) is an object-oriented set of libraries that allows you to interact with data sources.
- Commonly, the data source is a database, but it could also be a text file, an Excel spreadsheet, or an XML file.
- It is a part of the base class library that is included with the Microsoft .NET Framework.
- It is commonly used by programmers to access and modify data stored in relational database systems, though it can also access data in non-relational sources.
- The .NET Framework includes its own data access technology i.e. ADO.NET. ADO.NET is the
  latest implementation of Microsoft's Universal Data Access strategy. ADO.NET consists of
  managed classes that allows .NET applications to connect to data sources such as Microsoft SQL
  Server, Microsoft Access, Oracle, XML, etc., execute commands and manage disconnected data.
- Microsoft ADO.NET is the latest improvement after ADO. Firstly, ADO.NET was introduced in the 10<sup>th</sup> version of the .NET framework, which helps in providing an extensive array of various features to handle data in different modes, such as connected mode and disconnected mode. In connected mode, we are dealing with live data and in disconnected mode, data is provided from the data store. ADO.NET was primarily developed to address two ways to work with data that we are getting from data sources. The two ways are as follows:
- The first is to do with the user's need to access data once and to iterate through a collection of data in a single instance.
- The second way to work with data is disconnected architecture mode, in which we have to grab a collection of data and we use this data separately from the data store itself.

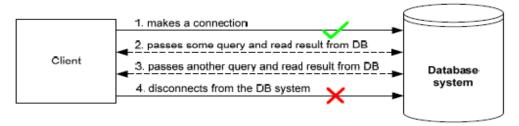

#### Architecture of ADO.NET :

- ADO.NET uses a multilayered architecture that revolves around a few key concepts as-asConnection, Command, DataSet objects
- The ADO.NET architecture is a little bit different from the ADO, which can be shown from the following figure of the architecture of ADO.NET:-

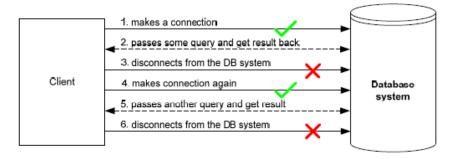

# Q-2 Explain Connected architecture in brief.

- In connected architecture, you made a connection to the database system and then interacted with it through SQL queries using connection.
- The application stays connected to the DB system even when it is not using DB services.
- This commonly wastes valuable and expensive database resources, as most of the time applications only query and view the persistent data.
- We read data from database using DataReader object.
- Connected architecture is read only, we can't update the data.

## Q-3 Explain Disconnected architecture in brief.

- ADO.NET solves connected architecture problem by managing a local buffer of persistent data called dataset.
- Application automatically connects to the database server when it needs to run a query and then disconnects immediately after getting the result back and storing in dataset.
- This design of ADO.NET is called a disconnected data architecture.
- It maintains a local repository of data in the dataset object.
- User can perform insert, update and delete operations.

## Q-4 What are the data providers in ado.net?

- ADO.NET allows us to interact with different types of data sources and different types of databases. However, there isn't a single set of classes that allow you to accomplish this universally.
- Since different data sources expose different protocols, there are more data sources every day that allow you to communicate with them directly through .NET ADO.NET class libraries.
- These libraries are called Data Providers and are usually named for the protocol or data source type they allow you to interact with.

Provider Name	API prefix	Data Source Description
ODBC Data Provider	Odbc	Data Sources with an ODBC interface. Normally older data bases.
OleDb Data Provider	OleDb	Data Sources that expose an OleDb interface, i.e. Access or Excel.
Oracle Data Provider	Oracle	For Oracle Databases.
SQL Data Provider	Sql	For interacting with Microsoft SQL Server.
Borland Data Provider	Bdp	Generic access to many databases such as Interbase, SQL Server, IBM DB2, and Oracle.

### Q-5 Explain Connection object in brief.

- Each data provider in ADO.NET contains a Connection class that inherits from the System.Data.Common.DbConnection class.
- The DbConnection serves as the base class for all the Connection classes of different data providers.
- To interact with a database, you must have a connection to it. The connection helps identify the database server, the database name, user name, password, and other parameters that are required for connecting to the data base.

Data Provider	Connection Class
SQL Server	SqlConnection
OLE DB	OleDbConnection
ODBC	OdbcConnection

# Q-6 Explain parameters of connection string / connection class.

- A SqlConnection is an object, just like any other C# object. Most of the time, you just declare and instantiate the SqlConnection all at the same time, as shown below:
- SqlConnection conn = new SqlConnection( "Data Source=(local);Initial Catalog=Northwind;Integrated Security=SSPI");

• The SqlConnection object instantiated above uses a constructor with a single argument of type string This argument is called a connection string.

Connection String Parameter Name	Description
Data Source	$\label{thm:condition} Identifies the server. \ Could be local machine, machine domain name, or \ IP \ Address.$
Initial Catalog	Database name.
Integrated Security	Set to SSPI to make connection with user's Windows login
User ID	Name of user configured in SQL Server.
Password	Password matching SQL Server User ID.

# Q-7 Explain Command object / Command class.

- Each data provider has their Command class which is use to execute SQL commands or stored procedures to the database.
- Each Command class inherits from the System.Data.Common.DbCommand base class.
- The following are the different flavors of the Command class for each data provider.

Data Provider	Command Class
Sql Server	SqlCommand
OLE DB	OleDbCommand
ODBC	OdbcCommand

- SqlCommand object allows you to specify what type of interaction you want to perform with a database.
- SqlCommand object can be used to support disconnected architecture.
- For example, you can do select, insert, modify, and delete commands on rows of data in a database table.
- SqlCommand cmd = new SqlCommand("select CategoryName from Categories", conn);
- for instantiating a SqlCommand object. It takes a string parameter that holds the command you want to execute and a reference to a SqlConnection object.
- The following are important built in methods uses in the Command Object to execute the SQL statements.

ExecuteReader	Executes the command and returns a forward-only read-only cursor in the form of a DataReader.
ExecuteNonQuery	Executes the command and returns the number of rows that were affected. Often used with record UPDATE, DELETE, or INSERT statements.
ExecuteScalar	Executes the command, and retrieves a single value. Used with aggregate functions and in cases where you want to return the first column of the first row of a result set.

Property	Description
CommandText	Specifies the SQL command or stored procedure or a name of a table.
CommandTimeout	Specifies the time required to wait for the completion of a command before it throws an exception. The default is 30 seconds.
CommandType	Accepts a value from the System.Data.CommandType enumeration that will determine the type of command specified in the CommandText property. It has 3 values, Text, for accepting SQL commands, StoredProcedure for stored procedures, and TableDirect to get all the rows and columns of one or multiple tables. Note that by default, Text will be used.
Connection	Specifies the connection that the command is associated to. The Command class must be hooked to an open connection which is the connection where the command is to be executed.
Parameters	A collection of Parameter defined in the CommandText.

# Q-8 Explain DataReder object with example.

- DataReader object allows forward-only, read-only access to a database.
- Using DataReader is the connected way of accessing data and an open connection must be available first.
- Each provider has its own version of DataReader which inherits to the System.Data.Common.DbDataReader base class.
- DataReader cannot be created directly from code, they can created only by calling the **ExecuteReader** method of a Command Object.

# SqlDataReader sqlReader = sqlCmd.ExecuteReader();

- Connection Object can contain only one DataReader at a time and the connection in the
  DataReader remains open, also it cannot be used for any other purpose while data is being
  accessed.
- **Read()** method in the DataReader is used to read the rows from DataReader and it always moves forward to a new valid row, if any row exist .

sqlReader.Read();

Method	Description
GetBoolean	Gets the value of a column as a boolean value.
GetChar	Gets the value of a column as a char value.
GetDataTypeName	Gets the name of the data type of the current column.
GetDateTime	Gets the value of the column as a DateTime object.
GetDecimal	Gets the value of the column as a decimal value.
GetDouble	Gets the value of the column as a double value.
GetFieldType	Gets the field type of the specified column.
GetInt32	Gets the value of the column as a int value.
GetName	Gets the name of the column.
GetOrdinal	Gets the column ordinal with the specified column name.
GetString	Gets the value of the column as a string value.
GetValue	Gets the value of a column as an object.
GetValues	Gets all the column of a row as an array of objects.
NextResult	Advances the reader to the next result when reading the results of a batch of statements.
Read	Advances the reader to the next record.

# Q-9 Explain DataAdapter and its properties.

- DataAdapter can be considered as a bridge between the actual data source to your application.
- It is commonly used together with a DataSet. Using DataAdapter and DataSet is the disconnected way of retrieving data from the data source.
- DataAdapter allows you to fill a DataSet with values from the data source, or execute different commands to the data source.
- To execute the command specified by the SelectCommand property, we can use the Fill() method of theDbDataAdapter class.
- The Fill() method requires an instance of the DataSet or DataTable classes. The following shows an example of filling a DataTable instance with values retrieved from the database.
- DataAdapter class inherits from the System.Data.Common.DbDataAdapter base class.
- Each data provider has its own version of DataAdapter.

Provider	DataAdapter Class
SQL Server	SqlDataAdapter
OLE DB	OleDbDataAdapter
ODBC	OdbcDataAdapter

Property	Description
DeleteCommand	Speicfies the Command object with the SQL command to be used for deleting a record.
FillCommandBehavior	Specifies the behavior of the command used to fill the data adapter.
Insert Command	Specifies the Command object with the SQL command yused for inserting a record.
SelectCommand	Specifies the Command object with the SQL command to be used for inserting a record.
UpdateBatchSize	Specifies the number of commands that can be executed as a batch.
UpdateCommand	Specifies the Command object with the SQL command to be used for inserting a record.

# Q-10 Give an Example of DataAdapter which reads data from database.

```
connection.Close();
for (i = 0; i <= ds.Tables[0].Rows.Count - 1; i++) {
    MessageBox.Show (ds.Tables[0].Rows[i].ItemArray[1].ToString());
    }
}
catch (Exception ex) {
    MessageBox.Show(ex.ToString());
}</pre>
```

#### Q-11 What is DataSet?

- System.Data.DataSet class holds data that are retrieved from the database.
- DataSet class allows you to hold disconnected data which means it store data at.NET application and perform database operation using dataAdapter..
- DataSet contains DataTableCollection and theirDataRelationCollection . It represents a complete set of data including the tables that contain, order, and constrain the data, as well as the relationships between the tables.
- Dataset contains more than one Table at a time. We can set up **Data Relations** between these tables within the DataSet. The data set may comprise data for one or more members, corresponding to the number of rows.
- DataAdapter Object allows us to populate DataTables in a DataSet. We can use Fill method of the DataAdapter for populating data in a Dataset. The DataSet can be filled either from a data source or dynamically.

## Q-12 Explain DataTable, DataColumn and DataRow with Example.

- DataTable objects are used to represent the tables in a DataSet.
- **DataTable** represents one table of in-memory relational data; the data is local to the .NET-based application in which it resides,
- DataTable is a relational database like table in the memory.
- It has a structural definition and constraints like unique constraints.
- We can create hierarchical relationships among many DataTables dynamically in a DataSet.
- To create DataTable,

DataTable myDataTable = new DataTable("Sample Table");

#### DataColumn

 Stored in collection named columns and represents the schema of a column in a DataTable.

#### **DataRow**

- DataRow represents a row of data in a DataTable.
- You can add data to the table using DataRow Object.
- DataRowCollection object represents a collection of data rows of a table.
- Use DataTable's NewRow metgod to return a DataRow object of data table,Add values to the data row and add a row to the data table.

## Syntax:

```
DataTable myDataTable = new DataTable("Sample_Table")
DataColumn myDataColumn new DataColumn();
DataRow my DataRow = myDataTable.NewRow();
```

### **Example:**

```
DataTable dt = new DataTable("Emp");

//Adding columns to table Emp
DataColumn colEmpid = new DataColumn("Empid",typeof(System.Int32));
DataColumn colName = new DataColumn("Name", typeof(System.String));
DataColumn colDept = new DataColumn("Department",typeof(System.String));

//Adding columns to datatable
dt.Columns.AddRange(new DataColumn[] { colEmpid, colName, colDept });

//Adding data
dt.Rows.Add( 1000, "John Smith Brown", "Finance" );
dt.Rows.Add( 1001, "Carry Brown", "Engineering" );
dt.Rows.Add(1002, "Candle Pencil", "Marketing");
dt.Rows.Add(1003, "Graham Bell", "Engineering");
dt.Rows.Add(1004, "Peter Kevin", "Finance & Engineering");
return dt;
```

#### Q-13 Explain DataView in brief.

- **DataView** provides different views of the data stored in a DataTable. That is we can customize the views of data from a DataTable.
- DataView can be used to sort, filter, and search the data in a **DataTable**, additionally we can add new rows and modify the content in a DataTable.
- We can create DataView in two different ways. We can use the **DataView Constructor**, or you can create a reference to the **DefaultView Property** of the DataTable.
- The DataView constructor can be empty, or it can take either a DataTable as a single argument, or a DataTable along with filter criteria, sort criteria, and a row state filter.
- dv = new DataView(dt, "Filter","Sort", DataViewRowState.CurrentRows);
- dv = dt.DefaultView;

```
OleDbConnection con = new OleDbConnection(@"Provider=Microsoft.Jet.OLEDB.4.0;Data Sour OleDbDataAdapter ad = new OleDbDataAdapter("Select * from Table1",con);
DataTable dt = new DataTable();
ad.Fill(dt);

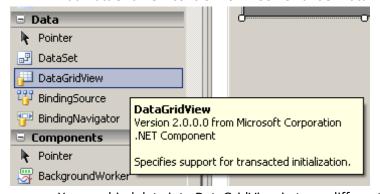

DataView dv = new DataView(dt,"ac_no > 3", "ac_no Desc",DataViewRowState.CurrentRows);
DataView dv = dt.DefaultView;
dataGridView1.DataSource = dt;
```

## Q-14 Explain DataGridView Control.

- DataGridView control is designed to be a complete solution for displaying tabular data with Windows Forms.
- DataGridView control is highly configurable and extensible, and it provides many properties, methods, and events to customize its appearance and behavior.
- DataGridView control makes it easy to define the basic appearance of cells and the display formatting of cell values.
- The cell is the fundamental unit of interaction for the DataGridView. All cells derive from the DataGridViewCell base class. Each cell within the DataGridView control can have its own style, such as text format, background color, foreground color, and font. Typically, however, multiple cells will share particular style characteristics.
- The data type for the cell's Value property by default is of type Object.

#### Q-15 Explain How to bind DataGridView in to application.

Add DataGridView control from ToolBox under Data Tab.

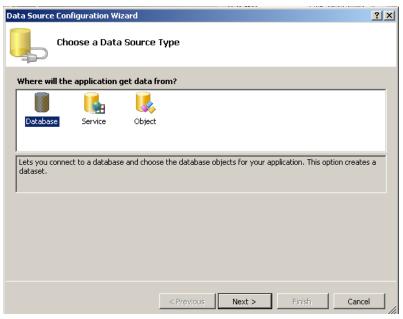

You can bind data into DataGridView in twop different ways:

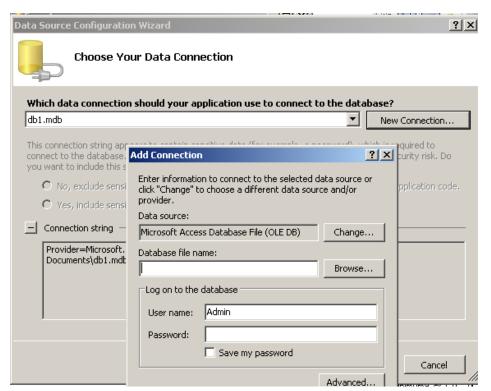

- Using DataGridView Configuration Wizard
- Dynamically by C# CODE
- Click on the DataSource property of DataGridView Control and click on Add Project DataSource

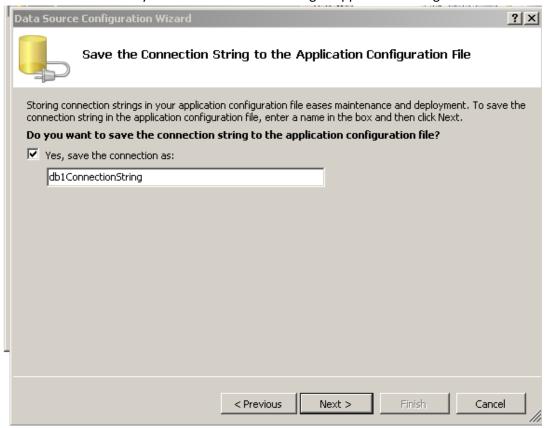

- You will get DataGridView Config Wizard Dialogbox
- Select Database and click Next> button.

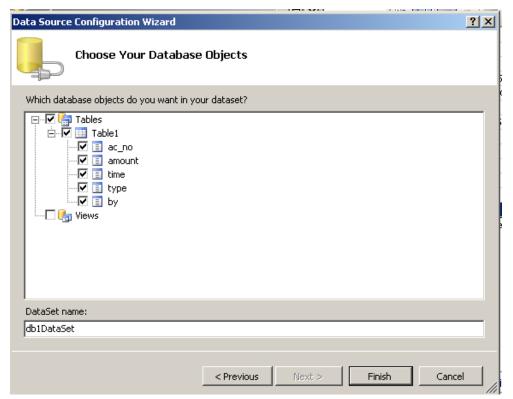

• Here you can create new database connection or you can select exsiting database connection. After selecting database connection click next.

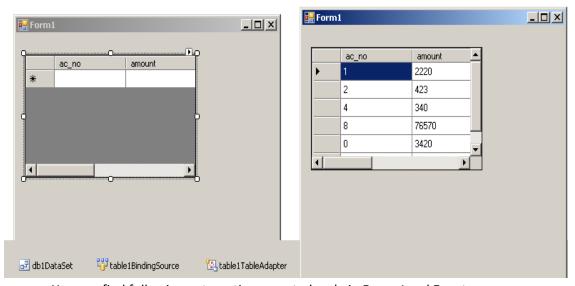

Then it will ask you to save connection string in application configration file or not.

• it will ask to choose database objects like tables/Views and it will make DataSet from chosen database objects and click finish.

 You can see it will automatically add DataSet, DataAdapter and binding source controls into application.

You can find following automatic generated code in Form\_Load Event

// TODO: This line of code loads data into the 'db1DataSet.Table1' table. You can move, or remove it, as needed.

this.table1TableAdapter.Fill(this.db1DataSet.Table1);

### DataGridView Programming

• Use DataSource property and bind DataTable or DataSet to it.

```
OleDbConnection con = new OleDbConnection(@"ConnectionString");

OleDbDataAdapter ad = new OleDbDataAdapter("Select * from Table1",con);

DataTable dt = new DataTable();

ad.Fill(dt);

dataGridView1.DataSource = dt;
```

## Q-16 Explain Repetear control in brief.

- The Repeater control is used to display a repeated list of items that are bound to the control. The Repeater control may be bound to a database table, an XML file, or another list of items.
- Repeater is a Data Bind Control. Data Bind Controls are container controls.
- Data Binding is the process of creating a link between the data source and the presentation
   UI to display the data.
- ASP.Net provides rich and wide variety of controls, which can be bound to the data.
- Repeater has 5 inline template to format it:
  - 1. <HeaderTemplate>
  - 2. <FooterTemplate>
  - 3. <ItemTemplate>
  - 4. < Alternating Item Template >
  - 5. <SeperatorTemplate>
  - 6. < Alternating Item Template >

• **HeaderTemplate:** This template is used for elements that you want to render once before your ItemTemplate section.

- **FooterTemplate:** This template is used for elements that you want to render once after your ItemTemplate section.
- **ItemTemplate:** This template is used for elements that are rendered once per row of data. It is used to display records
- AlternatingItemTemplate: This template is used for elements that are rendered every second row of data. This allows you to alternate background colors. It works on even number of records only.
- **SeperatorTemplate:** It is used for elements to render between each row, such as line breaks.

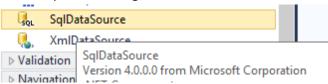

#### Q-17 How to bind data to DataBound Controls?

- Data-bound controls are Web controls those can easily bind with data components. Microsoft Visual Studio.NET is a rich IDE for ADO.NET data components.
- Data-bound controls have properties, which you can set as a data component and theyre ready to present your data in Web Controls(Gridview,ListBox,ComoboBox).
- DataSource and DisplayMemeber are two important properties.
  - DataSource property of these controls plays a major role. You can set different kind of data components as datasource property of a control. For example, you can set a DefaultViewManager or a DataView as this property.
  - DataTextField can be set to a database table field name if you want to bind a particular field to the control.
- Ex.

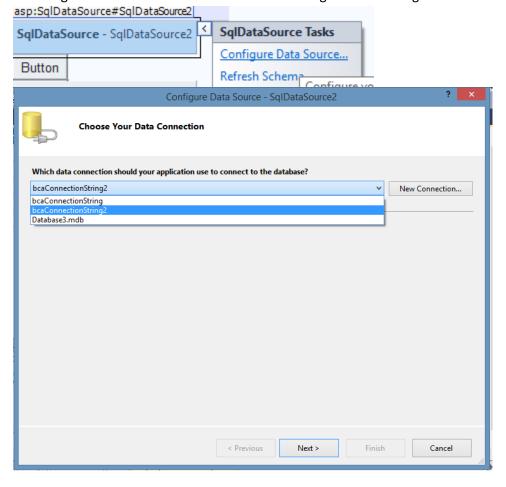

ListBox1.DataSource = ds; ListBox1.DataTextField = "Name"; ListBox.DataValue = "Id";

Q-18 how to Display Data using SQLDataSource?

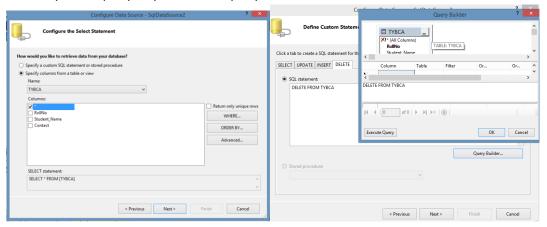

- The SqlDataSource control enables you to use a Web server control to access data that is located in a relational database.
- This can include Microsoft SQL Server and Oracle databases, as well as OLE DB and ODBC data sources.
- You can use the SqlDataSource control with data-bound controls such as the GridView, FormView, and DetailsView controls to display and manipulate data on an ASP.NET Web page, using little or no code.
- To add sqlDataSource goto ToolBox>DataControls

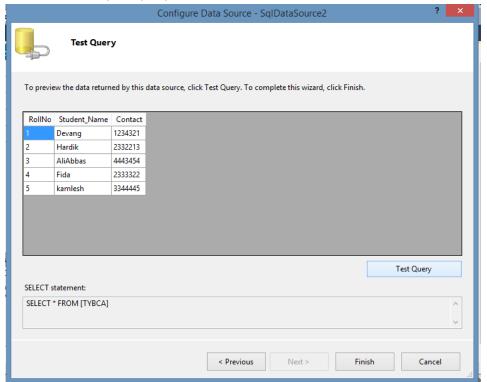

• To configure DataSource create db connection string or use exisiting connection string.

• You can select fields from interface or you can select first value SPECIFY SQL stmt where you can manually write query or you can use querybulider.

• You can test your query result.

## Q-19 What is DataBinding Expression?

- Data-binding syntax allows you to bind control property values to data and specify values for retrieving, updating, deleting, and inserting data.
- Data-binding expressions are contained within <%# and %> delimiters and use the Eval and Bind functions.
- **Eval** function is used to define one-way (read-only) binding.
- **Bind** function is used for two-way (updatable) binding.
- In addition to calling **Eval** and **Bind** methods to perform data binding in a data-binding expression, you can call any publicly scoped code within the <%# and %> delimiters to execute that code and return a value during page processing.
- Totalinder.Eval(Container,"DataItem.RollNo");
- **Eval** method evalutes the Eval method of DataBinder object, referencing the current data item of the naming container.
- The naming container is generally the smallest part of the data-bound control that contains a whole record, such as a row in a GridView control.
- You can therefore use the Eval method only for binding inside templates of a data-bound control.
- Data-binding expressions are resolved when the **DataBind** method of a control or of the Page class is called.
- For controls such as the GridView, DetailsView, and FormView controls, data-binding expressions are resolved automatically during the control's **PreRender** event and you are not required to call the **DataBind** method explicitly.
